

Project Abstract

Abstract: Finding and evaluating real estate properties can often be a time-consuming and physically demanding process for potential buyers and tenants. Our application is designed to make this process easier by providing a simple and user-friendly platform for property exploration. The application is built using Flutter for the mobile interface, while Spring Boot handles the backend operations, with a robust database used for managing property data efficiently.

The platform offers advanced features such as immersive 360-degree views of properties, allowing users to take secure virtual tours and remotely inspect every detail without needing an initial physical visit. A key part of the application is its AI-powered chatbot, which is designed to assist users in finding the right properties more easily. \n\nThe chatbot uses Natural Language Processing (NLP) to understand user preferences, recommend suitable properties, and answer specific queries about amenities and pricing. It also supports multiple languages, allowing users to interact comfortably, and guides them on the next steps they should take, such as scheduling a visit.

Overall, the application aims to bridge the gap between people and real estate by making property evaluation more interactive, understandable, and convenient for everyone.
